

2018

Q-No.01

(a)

Stratified Sampling

repeat (2016)

(b)

measurement scale / Error

measurement error occurs because of variation b/w the information sought by a researcher for a study and information taken by particular procedure used for measurement.

(c)

Processing of survey data

Data processing involves translating the answers on a questionnaire into a form that can be manipulated to produce statistics. In general,

This involves coding, editing data entry and monitoring the whole data processing procedure.

(d)

Types of Data collection

There are several Types of Data collection

- I Surveys.
- II Interviews
- III Observation
- IV Experiments
- V case studies
- VI Secondary Data collection

-i) Survey

Surveys are a common method of Data collection in which researchers ask participants a set of questions to gather information about their attitudes, behaviors.

-ii) Interviews

Interviews involve one-to-one interactions b/w researcher and participants.

Interview can be conducted in person, over the phone.

Observation

Observations involve researchers observing and recording data about participants behaviors in a natural.

Experiments :-

Experiments involve manipulating one or more variables to observe the effect on another variable.

Case-study

Case studies involve in-depth investigation of a single individual, group or organization. Case studies typically involve qualitative data collection methods, such as interviews and observation.

Secondary Data collection

Secondary data analysis involves analyzing existing data collected by other researchers for different purpose.

There are several types of rating scales used in research and evaluation. Here are some common types with examples:

1. **Likert scale:** This is a commonly used scale in which respondents indicate their level of agreement or disagreement with a statement on a five or seven-point scale, ranging from strongly disagree to strongly agree. Example: "I feel satisfied with my job" (Strongly disagree, Disagree, Neutral, Agree, Strongly agree).
2. **Semantic differential scale:** This scale measures the connotative meaning of a concept or object by asking respondents to rate it on a series of bipolar adjectives, such as good-bad, friendly-unfriendly, or useful-useless. Example: "The taste of this food is..." (Delicious-Terrible, Tasty-Disgusting, Flavorful-Flavorless)
3. **Visual analogue scale:** This scale uses a horizontal line or vertical bar, often accompanied by visual anchors at each end, to measure the intensity or frequency

Types of Statistical Scales.

Strongly agree).

2. Semantic differential scale: This scale measures the connotative meaning of a concept or object by asking respondents to rate it on a series of bipolar adjectives, such as good-bad, friendly-unfriendly, or useful-useless. Example: "The taste of this food is..." (Delicious-Terrible, Tasty-Disgusting, Flavorful-Flavorless)
3. Visual analogue scale: This scale uses a horizontal line or vertical bar, often accompanied by visual anchors at each end, to measure the intensity or frequency of a subjective experience, such as pain, anxiety, or happiness. Example: "Please rate the level of pain you are experiencing" (0: No pain at all, 10: Worst pain imaginable).
4. Numerical rating scale: This scale asks respondents to rate a particular item or statement using a numerical value, such as a score out of ten or a percentage. Example: "How likely are you to recommend this product to a friend?" (0-10 scale, 0: Not at all likely, 10: Extremely likely).

Q.2 What is a questionnaire? Which factors should be considered in questionnaire? Explain in detail.

A questionnaire is a data collection tool used to gather information from individuals about their attitudes, beliefs, behaviors, opinions, or experiences. It typically consists of a series of questions that respondents answer in writing, online, or verbally.

When designing a questionnaire, there are several factors that should be considered to ensure that it is an effective and reliable tool for gathering data. These factors include:

1. **Purpose:** The purpose of the questionnaire should be clearly defined before designing the questions. This will help ensure that the questions are focused and relevant to the research goals.

Solved by: M.Hurraira

Page 9

2. **Target population:** The questionnaire should be designed with the target population in mind. The questions should be appropriate for the age, education level, cultural background, and language proficiency of the respondents.
3. **Question format:** The format of the questions should be carefully considered. Open-ended questions allow respondents to provide detailed answers, but they can be difficult to analyze. Closed-ended questions with pre-defined response options are easier to analyze, but they may not capture the full range of possible responses.
4. **Question wording:** The wording of the questions should be clear and concise. Questions should be written in simple language and avoid jargon or technical terms that may be unfamiliar to the respondents.
5. **Question order:** The order of the questions should be carefully considered. The questions should be organized in a logical and coherent manner that flows well and avoids confusion.
6. **Response options:** The response options for closed-ended questions should be carefully chosen to ensure that they capture the full range of possible responses. They should also be mutually exclusive and collectively exhaustive.
7. **Length:** The length of the questionnaire should be appropriate for the target population and the purpose of the research. Long questionnaires can lead to respondent fatigue and reduced response rates.
8. **Pretesting:** The questionnaire should be pretested with a small sample of respondents to identify any issues with the design, wording, or format of the questions.

In summary, designing an effective questionnaire involves careful consideration of the purpose, target population, question format, question wording, question order, response options, length, and pretesting. By following these guidelines, researchers can create a reliable and valid tool for gathering data.
