

(2017)

Q-No. 01

(a)

Sampling frame:-

repeat - 2015

(b)

Census:

The collection of information from all the elements of population is called census.

Advantages

- Census provides a true measure of the population.
- benchmark data may be obtained for future studies.

Disadvantages

- Census may be difficult to enumerate all units of the population within the available time.
- Census is impossible for infinite population.

(c)
pretesting of questionnaire
repeat - (2015)

(d)
Literature review

A literature review involves identifying, analyzing and evaluating sources of information that are relevant to the research question or topic being investigated.

This includes academic journals, books, government reports and other credible sources of information.

PUACP

Open-Ended Questions (2017) long

→ In an open-ended Questions the possible responses are not given.

→ The respondent writes down the answers in his own words.

FOR Example:-

* what you like to do in your spare time? _____

PUACP

CLOSED-ENDED Questions:- 2016 (d) 2017 long

- In a closed question the possible answers are set out in the questionnaire
- closed-ended questions have short check mark responses.
- There is no provision other than the given answers for the respondent.
- The respondent or the investigator ticks the category that best describes the respondent's answer.
- closed-questions can also be used in interviews as well as questionnaire.
- These are widely used types of questions
- These may also known as multiple choice questions.

FOR Example:-

→ what is your designation?

☐ lecture ☐ Assistant prof ☐ Associate prof

Advantages of Open-ENDED, 2017) Questions :-

→ Open-ended Questions provide greater depth of response.

→ If respondents are fluent in the language used and feel comfortable about expressing their opinions then open-ended questions can provide in-depth information.

→ Open-ended questions provide respondents with the opportunity to express themselves freely, resulting in a greater variety of information.

→ As open-ended questions eliminate the possibility of investigator bias.

(Investigator bias is introduced pattern presented to respondents.)

(2017)

Disadvantages of open-Ended

Questions :-

→ These are difficult to tabulate, summaries analyze and interpret,

→ The researcher usually needs to go through another process - content analysis - in order to classify the data.

→ In a questionnaire, some respondents may not be able to express themselves, and so information can be lost.

→ There is a greater chance of interviewer bias in open-ended questions.

→ Open-ended questions require great effort on the part of respondent as well as researcher

(2017) Advantages of closed-Ended Question :-

→ These are easy to fill out and analyze.

→ close-ended questions provide the relevant information only.

→ These do not require much time.

→ These are more acceptable for the respondent.

→ These are popular because these provide a greater uniformity of responses.

→ These are easy to summarize, tabulate, analyze and interpret.

Disadvantages of closed-ended Questions

→ one of the main disadvantages of closed questions is that the information obtained through them lacks depth and variety.

→ There is a greater possibility of investigator bias because the researcher may list only the response patterns that he is interested in or those that come to mind.

→ The ease of answering a ready-made list of responses may create a tendency among some respondents and interviewers to tick a category or categories without thinking through the issue.

→ In a questionnaire, the given response pattern for a question could condition the thinking of respondents, and so the answers provided may not truly reflect respondents' opinions. Rather they may reflect the extent of agreement or disagreement with the researcher's opinion or analysis of a situation.

Q.2 Explain open ended and close ended questions, their advantage and disadvantage and the situation in which they are used.

Q.3 What do you understand by the term determination of sample size which factors are involve in it? Explain in detail.

In statistics, determining the sample size refers to the process of deciding on the number of participants or units that need to be included in a study to obtain results that are both statistically significant and reliable. The sample size is a crucial component of any research study, as it impacts the accuracy and generalizability of the results.

There are several factors that are involved in determining the appropriate sample size for a study. These factors include:

1. **Population size:** The size of the population that the study is targeting is an important consideration in determining sample size. If the population is small, then a larger proportion of the population may need to be sampled to achieve a representative sample.
2. **Level of precision:** The desired level of precision, or how closely the sample results need to match the population parameters, will also impact the sample size. Generally, as the level of precision increases, the sample size required will also increase.
3. **Margin of error:** The margin of error is the degree of accuracy required in the results. The smaller the margin of error, the larger the sample size required to achieve it.
4. **Confidence level:** The confidence level is the probability that the results from the sample will be representative of the population. Higher confidence levels require larger sample sizes to achieve.
5. **Variability of the population:** The variability of the population being studied will also impact the sample size required. If the population is highly variable, then a larger sample size may be required to ensure representativeness.
6. **Type of data:** The type of data being collected will also affect sample size. For example, if the data is binary (i.e., yes or no responses), then a smaller sample size may be sufficient compared to continuous data (such as height or weight), which may require a larger sample size.

Determining the appropriate sample size for a study requires consideration of several factors, including population size, level of precision, margin of error, confidence level, variability of the
